Abstract

The **protr** package offers a unique and comprehensive toolkit for generating various numerical representation schemes of protein sequence. The descriptors included are extensively utilized in Bioinformatics and Chemogenomics research. The commonly used descriptors listed in **protr** include amino acid composition, autocorrelation, CTD, conjoint traid, quasi-sequence order, pseudo amino acid composition, and profile-based descriptors derived by Position-Specific Scoring Matrix (PSSM). The descriptors for proteochemometric (PCM) modeling, includes the scales-based descriptors derived by principal components analysis, factor analysis, multidimensional scaling, amino acid properties (AAindex), 20+ classes of 2D and 3D molecular descriptors (Topological, WHIM, VHSE, etc.), and BLOSUM/PAM matrix-derived descriptors. The **protr** package also integrates the function of parallelized similarity computation derived by pairwise protein sequence alignment and Gene Ontology (GO) semantic similarity measures. **ProtrWeb**, the web server built on **protr**, is located at: <http://protr.org>.

Keywords: protein sequence, amino acid, descriptor, structural similarity, functional similarity, sequence alignment, Gene Ontology

1. The Full Workflow Using protr

Here we use the subcellular localization dataset of human proteins presented in the study of Chou and Shen (2008) to demonstrate the full workflow when using protr.

The complete dataset includes 3134 protein sequences (2750 different proteins), classified into 14 human subcellular locations. We select two classes of proteins as our benchmark dataset. Class 1 contains 325 *extracell* proteins, and class 2 includes 307 *mitochondrion* proteins.

First, we load the **protr** package, then read the protein sequences stored in two separated FASTA files with `readFASTA()`:

```
require(protr)

# load FASTA files
extracell = readFASTA(system.file('protseq/extracell.fasta',
                                  package = 'protr'))
mitonchon = readFASTA(system.file('protseq/mitochondrion.fasta',
                                  package = 'protr'))
```

To read protein sequences stored in PDB format files, use `readPDB()` instead. The loaded sequences will be stored as two lists in R, and each component in the list is a character string representing one protein sequence. In this case, there are 325 *extracell* protein sequences and 306 *mitonchon* protein sequences:

```
length(extracell)

## [1] 325

length(mitonchon)
```

```
## [1] 306
```

To assure that the protein sequences only have the twenty standard amino acid types which is required for the descriptor computation, we use the `protcheck()` function in **protr** to do the amino acid type sanity checking and remove the *non-standard* sequences:

```
extracell = extracell[(sapply(extracell, protcheck))]  
mitonchon = mitonchon[(sapply(mitonchon, protcheck))]
```

```
length(extracell)
```

```
## [1] 323
```

```
length(mitonchon)
```

```
## [1] 304
```

Two protein sequences were removed from each class. For the remaining sequences, we calculate the Type II PseAAC descriptor, i.e., the amphiphilic pseudo amino acid composition (APAAC) descriptor ([Chou 2005](#)) and make class labels for classification modeling.

```
# calculate APAAC descriptors  
x1 = t(sapply(extracell, extractAPAAC))  
x2 = t(sapply(mitonchon, extractAPAAC))  
x  = rbind(x1, x2)  
  
# make class labels  
labels = as.factor(c(rep(0, length(extracell)), rep(1, length(mitonchon))))
```

In **protr**, the functions of commonly used descriptors for protein sequences and proteochemometric (PCM) modeling descriptors are named after `extract...()`.

Next, we will split the data into a 75% training set and a 25% test set.

```
# split training and test set  
set.seed(1001)  
tr.idx = c(sample(1:nrow(x1), round(nrow(x1) * 0.75)),  
            sample(nrow(x1) + 1:nrow(x2), round(nrow(x2) * 0.75)))  
te.idx = setdiff(1:nrow(x), tr.idx)  
x.tr   = x[tr.idx, ]  
x.te   = x[te.idx, ]  
y.tr   = labels[tr.idx]  
y.te   = labels[te.idx]
```

We will train a random forest classification model on the training set with 5-fold cross-validation, using the **randomForest** package.

```
require(randomForest)
rf.fit = randomForest(x.tr, y.tr, cv.fold = 5)
print(rf.fit)
```

The training result is:

```
## Call:
## randomForest(x = x.tr, y = y.tr, cv.fold = 5)
##               Type of random forest: classification
##               Number of trees: 500
## No. of variables tried at each split: 8
##
## OOB estimate of error rate: 25.11%
## Confusion matrix:
##      0   1 class.error
## 0 196  46  0.1900826
## 1  72 156  0.3157895
```

With the model trained on the training set, we predict on the test set and plot the ROC curve with the **pROC** package, as is shown in figure 1.

```
# predict on test set
rf.pred = predict(rf.fit, newdata = x.te, type = 'prob')[, 1]

# plot ROC curve
require(pROC)
plot.roc(y.te, rf.pred, col = '#0080ff', grid = TRUE, print.auc = TRUE)
```

The area under the ROC curve (AUC) is:

```
## Call:
## plot.roc.default(x = y.te, predictor = rf.pred, col = "#0080ff",
##               grid = TRUE, print.auc = TRUE)
##
## Data: rf.pred in 81 controls (y.te 0) > 76 cases (y.te 1).
## Area under the curve: 0.8697
```

2. Package Overview

The **protr** package (Xiao *et al.* 2014) implemented most of the state-of-the-art protein sequence descriptors with R. The **protr** package is freely available from the Comprehensive R Archive Network (<http://CRAN.R-project.org/package=protr>). This vignette corresponds to **protr** version 1.2-0 and was typeset on 2016-11-12.

Generally, each type of the descriptors (features) could be calculated with a function named **extractX()** in the **protr** package, where X stands for the abbreviation of the descriptor name. The descriptors and the function names implemented are listed below:

Figure 1: ROC curve for the test set of protein subcellular localization data

- Amino acid composition
 - `extractAAC()` - Amino acid composition
 - `extractDC()` - Dipeptide composition
 - `extractTC()` - Tripeptide composition
- Autocorrelation
 - `extractMoreauBroto()` - Normalized Moreau-Broto autocorrelation
 - `extractMoran()` - Moran autocorrelation
 - `extractGeary()` - Geary autocorrelation
- CTD
 - `extractCTDC()` - Composition
 - `extractCTDT()` - Transition
 - `extractCTDD()` - Distribution
- Conjoint triad descriptors
 - `extractCTriad()` - Conjoint triad descriptors
- Quasi-sequence-order descriptors
 - `extractSOCN()` - Sequence-order-coupling number

- `extractQSO()` - Quasi-sequence-order descriptors
- Pseudo-amino acid composition
 - `extractPAAC()` - Pseudo-amino acid composition
 - `extractAPAAC()` - Amphiphilic pseudo-amino acid composition
- Profile-based descriptors
 - `extractPSSM()`
 - `extractPSSMAcc()`
 - `extractPSSMFeature()`

The descriptors commonly used in Proteochemometric Modeling (PCM) implemented in **protr** include:

- `extractScales()` and `extractScalesGap()` - Scales-based descriptors derived by Principal Components Analysis
 - `extractProtFP()` and `extractProtFPGap()` - Scales-based descriptors derived by amino acid properties from AAindex (a.k.a. Protein Fingerprint)
 - `extractDescScales()` - Scales-based descriptors derived by 20+ classes of 2D and 3D molecular descriptors (Topological, WHIM, VHSE, etc.)
- `extractFAScales()` - Scales-based descriptors derived by Factor Analysis
- `extractMDSScales()` - Scales-based descriptors derived by Multidimensional Scaling
- `extractBLOSUM()` - BLOSUM and PAM matrix-derived descriptors

The **protr** package integrates the function of parallelized similarity score computation derived by local or global protein sequence alignment between a list of protein sequences, the sequence alignment computation is provided by **Biostrings**, the corresponding functions listed in the **protr** package include:

- `twoSeqSim()` - Similarity calculation derived by sequence alignment between two protein sequences
- `parSeqSim()` - Parallelized pairwise similarity calculation with a list of protein sequences

The **protr** package also integrates the function of parallelized similarity score computation derived by Gene Ontology (GO) semantic similarity measures between a list of GO terms / Entrez Gene IDs, the GO similarity computation is provided by **GOSemSim**, the corresponding functions listed in the **protr** package include:

- `twoGOSim()` - Similarity calculation derived by GO-terms semantic similarity measures between two GO terms / Entrez Gene IDs
- `parGOSim()` - Pairwise similarity calculation with a list of GO terms / Entrez Gene IDs

To use the `parSeqSim()` function, we suggest the users to install the packages **foreach** and **doParallel** first, in order to make the parallelized pairwise similarity computation available.

In the next sections, we'll introduce the descriptors and function usage in this order.

3. Commonly Used Descriptors

Disclaimer. Users of the **protr** package need to intelligently evaluate the underlying details of the descriptors provided, instead of using **protr** with their data blindly, especially for the descriptor types with more flexibility. It would be wise for the users to use some negative and positive control comparisons where relevant to help guide interpretation of the results.

A protein or peptide sequence with N amino acid residues could be generally represented as $\{R_1, R_2, \dots, R_n\}$, where R_i represents the residue at the i -th position in the sequence. The labels i and j are used to index amino acid position in a sequence, and r, s, t are used to represent the amino acid type. The computed descriptors are roughly divided into 4 groups according to their known applications described in the literature.

A protein sequence could be divided equally into segments and the methods, described as follows for the global sequence, could be applied to each segment.

3.1. Amino Acid Composition (AAC)

The Amino Acid Composition (AAC) is the fraction of each amino acid type within a protein. The fractions of all 20 natural amino acids are calculated as:

$$f(r) = \frac{N_r}{N} \quad r = 1, 2, \dots, 20.$$

where N_r is the number of the amino acid type r and N is the length of the sequence.

As was described above, we could use the function `extractAAC()` to extract the descriptors (features) from protein sequences:

```
> require(protr)
> x = readFASTA(system.file('protseq/P00750.fasta', package = 'protr'))[[1]]
> extractAAC(x)
```

A	R	N	D	C	E	Q
0.06405694	0.07117438	0.03914591	0.05160142	0.06761566	0.04804270	0.04804270
G	H	I	L	K	M	F
0.08185053	0.03024911	0.03558719	0.07651246	0.03914591	0.01245552	0.03202847
P	S	T	W	Y	V	
0.05338078	0.08896797	0.04448399	0.02313167	0.04270463	0.04982206	

Here with the function `readFASTA()` we loaded a single protein sequence (P00750, Tissue-type plasminogen activator) from a FASTA format file. Then extracted the AAC descriptors with `extractAAC()`. The result returned is a named vector, whose elements are tagged with the name of each amino acid.

3.2. Dipeptide Composition (DC)

The Dipeptide Composition (DC) gives 400 descriptors, defined as:

$$f(r, s) = \frac{N_{rs}}{N - 1} \quad r, s = 1, 2, \dots, 20.$$

where N_{rs} is the number of dipeptide represented by amino acid type r and type s . Similar to `extractAAC()`, here we use `extractDC()` to compute the descriptors:

```
> dc = extractDC(x)
> head(dc, n = 30L)
```

0.000000000	0.000000000	0.003565062	0.007130125	0.005347594	0.001782531
CR	ER	QR	GR	HR	IR
0.005347594	0.005347594	0.000000000	0.007130125	0.001782531	0.003565062

Here we only showed the first 30 elements of the result vector and omitted the rest of the result. The element names of the returned vector are self-explanatory as before.

3.3. Tripeptide Composition (TC)

The Tripeptide Composition (TC) gives 8000 descriptors, defined as:

$$f(r, s, t) = \frac{N_{rst}}{N - 2} \quad r, s, t = 1, 2, \dots, 20$$

where N_{rst} is the number of tripeptides represented by amino acid type r , s and t . With function `extractTC()`, we could easily obtain the length-8000 descriptor, to save some space, here we also omitted the tedious outputs:

```
> tc = extractTC(x)
> head(tc, n = 36L)
```

```

3.4. Autocorrelation Descriptors

Autocorrelation descriptors are defined based on the distribution of amino acid properties along the sequence. The amino acid properties used here are various types of amino acids index (Retrieved from AAindex Database: <http://www.genome.jp/dbget/aaindex.html>, see Kawashima *et al.* (1999), Kawashima and Kanehisa (2000), and Kawashima *et al.* (2008), see Figure 2 for an illustrated example). Three types of autocorrelation descriptors are defined here and described below.

All the amino acid indices are centralized and standardized before the calculation, i.e.

$$P_r = \frac{P_r - \bar{P}}{\sigma}$$

where \bar{P} is the average of the property of the 20 amino acids:

$$\bar{P} = \frac{\sum_{r=1}^{20} P_r}{20} \quad \text{and} \quad \sigma = \sqrt{\frac{1}{2} \sum_{r=1}^{20} (P_r - \bar{P})^2}$$

```

Figure 2: An illustrated example in the AAIndex database

Normalized Moreau-Broto Autocorrelation Descriptors

Moreau-Broto autocorrelation descriptors application to protein sequences could be defined as:

$$AC(d) = \sum_{i=1}^{N-d} P_i P_{i+d} \quad d = 1, 2, \dots, \text{nlag}$$

where d is called the lag of the autocorrelation and P_i and P_{i+d} are the properties of the amino acids at position i and $i + d$, respectively. `nlag` is the maximum value of the lag.

The normalized Moreau-Broto autocorrelation descriptors are defined as:

$$ATS(d) = \frac{AC(d)}{N - d} \quad d = 1, 2, \dots, \text{nlag}$$

The corresponding function for this descriptor is `extractMoreauBroto()`. A typical call could be:

```
> moreau = extractMoreauBroto(x)
> head(moreau, n = 36L)
```

The 8 default properties used here are:

- **AccNo. CIDH920105** — Normalized Average Hydrophobicity Scales
- **AccNo. BHAR880101** — Average Flexibility Indices
- **AccNo. CHAM820101** — Polarizability Parameter
- **AccNo. CHAM820102** — Free Energy of Solution in Water, kcal/mole
- **AccNo. CHOC760101** — Residue Accessible Surface Area in Tripeptide
- **AccNo. BIGC670101** — Residue Volume
- **AccNo. CHAM810101** — Steric Parameter
- **AccNo. DAYM780201** — Relative Mutability

Users could change the property names of AAindex database with the argument **props**. The AAindex data shipped with **protr** could be loaded by `data(AAindex)`, which has the detailed information of each property. With the argument **customprops** and **nlag**, users could specify their own properties and lag value to calculate with. For illustration, we could use:

```
> # Define 3 custom properties
> myprops = data.frame(AccNo = c("MyProp1", "MyProp2", "MyProp3"),
+                      A = c(0.62, -0.5, 15), R = c(-2.53, 3, 101),
+                      N = c(-0.78, 0.2, 58), D = c(-0.9, 3, 59),
+                      C = c(0.29, -1, 47), E = c(-0.74, 3, 73),
+                      Q = c(-0.85, 0.2, 72), G = c(0.48, 0, 1),
+                      H = c(-0.4, -0.5, 82), I = c(1.38, -1.8, 57),
+                      L = c(1.06, -1.8, 57), K = c(-1.5, 3, 73),
+                      M = c(0.64, -1.3, 75), F = c(1.19, -2.5, 91),
+                      P = c(0.12, 0, 42), S = c(-0.18, 0.3, 31),
+                      T = c(-0.05, -0.4, 45), W = c(0.81, -3.4, 130),
+                      Y = c(0.26, -2.3, 107), V = c(1.08, -1.5, 43))
> # Use 4 properties in the AAindex database, and 3 customized properties
> moreau2 = extractMoreauBroto(x, customprops = myprops,
+                              props = c('CIDH920105', 'BHAR880101',
+                                         'CHAM820101', 'CHAM820102',
+                                         'MyProp1', 'MyProp2', 'MyProp3'))
> head(moreau2, n = 36L)
```

About the standard input format of **props** and **customprops**, see `?extractMoreauBroto` for details.

Moran Autocorrelation Descriptors

Moran autocorrelation descriptors application to protein sequence may be defined as:

$$I(d) = \frac{\frac{1}{N-d} \sum_{i=1}^{N-d} (P_i - \bar{P}')(P_{i+d} - \bar{P}')}{\frac{1}{N} \sum_{i=1}^N (P_i - \bar{P}')^2} \quad d = 1, 2, \dots, 30$$

where d and P_i and P_{i+d} are defined in the same way as in the first place, and \bar{P}' is the considered property P along the sequence, i.e.,

$$\bar{P}' = \frac{\sum_{i=1}^N P_i}{N}$$

d , P , P_i and P_{i+d} , $nlag$ have the same meaning as above.

With `extractMoran()`, which has exactly the same arguments with `extractMoreauBroto()`, we could compute the Moran autocorrelation descriptors (only output the first 36 elements of the result):

```
> # Use the 3 custom properties defined before
> # and 4 properties in the AAindex database
> moran = extractMoran(x, customprops = myprops,
+                      props = c('CIDH920105', 'BHAR880101',
+                                'CHAM820101', 'CHAM820102',
+                                'MyProp1', 'MyProp2', 'MyProp3'))
> head(moran, n = 36L)
```

Geary Autocorrelation Descriptors

Geary autocorrelation descriptors for protein sequence could be defined as:

$$C(d) = \frac{\frac{1}{2(N-d)} \sum_{i=1}^{N-d} (P_i - P_{i+d})^2}{\frac{1}{N-1} \sum_{i=1}^N (P_i - \bar{P})^2} \quad d = 1, 2, \dots, 30$$

where d , P , P_i and P_{i+d} , $nlag$ have the same meaning as above.

For each amino acid index, there will be $3 \times nlag$ autocorrelation descriptors. The usage of `extractGeary()` is exactly the same with `extractMoreauBroto()` and `extractMoran()`:

```
> # Use the 3 custom properties defined before
> # and 4 properties in the AAindex database
> geary = extractGeary(x, customprops = myprops,
+                     props = c('CIDH920105', 'BHAR880101',
+                               'CHAM820101', 'CHAM820102',
+                               'MyProp1', 'MyProp2', 'MyProp3'))
> head(geary, n = 36L)
```

3.5. Composition / Transition / Distribution

These descriptors are developed and described by [Dubchak *et al.* \(1995\)](#) and [Dubchak *et al.* \(1999\)](#).

Step 1: Sequence Encoding

The amino acids are divided in three classes according to its attribute and each amino acid is encoded by one of the indices 1, 2, 3 according to which class it belonged. The attributes used

Sequence	M	T	E	I	T	A	S	M	V	K	E	L	R	E	A	T	G	T	G	A
Sequence Index	1				5					10					15					20
Transformation	3	2	1	3	2	2	2	3	3	1	1	3	1	1	2	2	2	2	2	2
Index for 1			1							2	3		4	5						
Index for 2		1			2	3	4								5	6	7	8	9	10
Index for 3	1			2				3	4			5								
1/2 Transitions																				
1/3 Transitions																				
2/3 Transitions																				

Figure 3: The sequence of a hypothetical protein indicating the construction of composition, transition and distribution descriptors of a protein. Sequence index indicates the position of an amino acid in the sequence. The index for each type of amino acids in the sequence (‘1’, ‘2’ or ‘3’) indicates the position of the first, second, third, ... of that type of amino acid. 1/2 transition indicates the position of ‘12’ or ‘21’ pairs in the sequence (1/3 and 2/3 are defined in the same way.).

Table 1: Amino acid attributes and the division of the amino acids into three groups for each attribute

	Group 1	Group 2	Group 3
Hydrophobicity	Polar R, K, E, D, Q, N	Neutral G, A, S, T, P, H, Y	Hydrophobicity C, L, V, I, M, F, W
Normalized van der Waals Volume	0-2.78 G, A, S, T, P, D, C	2.95-4.0 N, V, E, Q, I, L	4.03-8.08 M, H, K, F, R, Y, W
Polarity	4.9-6.2 L, I, F, W, C, M, V, Y	8.0-9.2 P, A, T, G, S	10.4-13.0 H, Q, R, K, N, E, D
Polarizability	0-1.08 G, A, S, D, T	0.128-0.186 C, P, N, V, E, Q, I, L	0.219-0.409 K, M, H, F, R, Y, W
Charge	Positive K, R	Neutral A, N, C, Q, G, H, I, L, M, F, P, S, T, W, Y, V	Negative D, E
Secondary Structure	Helix E, A, L, M, Q, K, R, H	Strand V, I, Y, C, W, F, T	Coil G, N, P, S, D
Solvent Accessibility	Buried A, L, F, C, G, I, V, W	Exposed R, K, Q, E, N, D	Intermediate M, S, P, T, H, Y

here include hydrophobicity, normalized van der Waals volume polarity, and polarizability, as in the references. The corresponding division is in the table 1.

For example, for a given sequence “MTEITAAMVKELRESTGAGA”, it will be encoded as “32132223311311222222” according to its hydrophobicity division.

Step 2: Compute Composition, Transition and Distribution Descriptors

Three descriptors, *Composition* (C), *Transition* (T), and *Distribution* (D) were calculated for a given attribute as follows.

Composition

It is the global percent for each encoded class in the sequence. In the above example using hydrophobicity division, the numbers for encoded classes “1”, “2”, “3” are 5, 10, 5 respectively, so the compositions for them are $5/20 = 25\%$, $10/20 = 10\%$, and $5/20 = 25\%$ respectively, where 20 is the length of the protein sequence. Composition can be defined as

$$C_r = \frac{n_r}{n} \quad r = 1, 2, 3$$

where n_r is the number of amino acid type r in the encoded sequence and N is the length of the sequence. An example for `extractCTDC()` could be:

```
> extractCTDC(x)
```

hydrophobicity.Group1	hydrophobicity.Group2	hydrophobicity.Group3
0.29715302	0.40569395	0.29715302
normwaalsvolume.Group1	normwaalsvolume.Group2	normwaalsvolume.Group3
0.45195730	0.29715302	0.25088968
polarity.Group1	polarity.Group2	polarity.Group3
0.33985765	0.33274021	0.32740214
polarizability.Group1	polarizability.Group2	polarizability.Group3
0.33096085	0.41814947	0.25088968
charge.Group1	charge.Group2	charge.Group3
0.11032028	0.79003559	0.09964413
secondarystruct.Group1	secondarystruct.Group2	secondarystruct.Group3
0.38967972	0.29537367	0.31494662
solventaccess.Group1	solventaccess.Group2	solventaccess.Group3
0.43060498	0.29715302	0.27224199

The result shows the elements whose names are `PropertyNumber.GroupNumber` in the returned vector.

Transition

A transition from class 1 to 2 is the percent frequency with which 1 is followed by 2 or 2 is followed by 1 in the encoded sequence. Transition descriptor can be calculated as

$$T_{rs} = \frac{n_{rs} + n_{sr}}{N - 1} \quad rs = '12', '13', '23'$$

where n_{rs} , n_{sr} is the numbers of dipeptide encoded as “rs” and “sr” respectively in the sequence and N is the length of the sequence. An example for `extractCTDT()` could be:

```
> extractCTDT(x)
```

```
prop1.Tr1221 prop1.Tr1331 prop1.Tr2332 prop2.Tr1221 prop2.Tr1331 prop2.Tr2332

prop7.Tr1221 prop7.Tr1331 prop7.Tr2332
0.25133690 0.21568627 0.18003565
```

Distribution

The “distribution” descriptor describes the distribution of each attribute in the sequence.

There are five “distribution” descriptors for each attribute and they are the position percents in the whole sequence for the first residue, 25% residues, 50% residues, 75% residues and 100% residues, respectively, for a specified encoded class. For example, there are 10 residues encoded as “2” in the above example, the positions for the first residue “2”, the 2th residue “2” (25%*10=2), the 5th “2” residue (50%*10=5), the 7th “2” (75%*10=7) and the 10th residue “2” (100%*10) in the encoded sequence are 2, 5, 15, 17, 20 respectively, so the distribution descriptors for “2” are: 10.0 (2/20*100), 25.0 (5/20*100), 75.0 (15/20*100), 85.0 (17/20*100), 100.0 (20/20*100), respectively.

Finally, an example for `extractCTDD()` could be:

```
> extractCTDD(x)
```

```

3.6. Conjoint Triad Descriptors

Conjoint triad descriptors are proposed by [Shen *et al.* \(2007\)](#). These conjoint triad descriptors

abstracts the features of protein pairs based on the classification of amino acids. In this approach, each protein sequence is represented by a vector space consisting of descriptors of amino acids. To reduce the dimensions of vector space, the 20 amino acids were clustered into several classes according to their dipoles and volumes of the side chains. The conjoint triad descriptors are calculated as follows:

Step 1: Classification of Amino Acids

Electrostatic and hydrophobic interactions dominate protein-protein interactions. These two kinds of interactions may be reflected by the dipoles and volumes of the side chains of amino acids, respectively. Accordingly, these two parameters were calculated, respectively, by using the density-functional theory method B3LYP/6-31G and molecular modeling approach. Based on the dipoles and volumes of the side chains, the 20 amino acids could be clustered into seven classes (See Table 2). Amino acids within the same class likely involve synonymous mutations because of their similar characteristics.

Table 2: Classification of amino acids based on dipoles and volumes of the side chains

No.	Dipole Scale ¹	Volume Scale ²	Class
1	—	—	Ala, Gly, Val
2	—	+	Ile, Leu, Phe, Pro
3	+	+	Tyr, Met, Thr, Ser
4	++	+	His, Asn, Gln, Tpr
5	+++	+	Arg, Lys
6	+′ +′ +′	+	Asp, Glu
7	+ ³	+	Cys

Step 2: Conjoint Triad Calculation

The conjoint triad descriptors considered the properties of one amino acid and its vicinal amino acids and regarded any three continuous amino acids as a unit. Thus, the triads can be differentiated according to the classes of amino acids, i.e., triads composed by three amino acids belonging to the same classes, such as ART and VKS, could be treated identically. To conveniently represent a protein, we first use a binary space (\mathbf{V}, \mathbf{F}) to represent a protein sequence. Here, \mathbf{V} is the vector space of the sequence features, and each feature v_i represents a sort of triad type; \mathbf{F} is the frequency vector corresponding to \mathbf{V} , and the value of the i -th dimension of $\mathbf{F}(f_i)$ is the frequency of type v_i appearing in the protein sequence. For the amino acids that have been categorized into seven classes, the size of \mathbf{V} should be $7 \times 7 \times 7$; thus $i = 1, 2, \dots, 343$. The detailed description for (\mathbf{V}, \mathbf{F}) is illustrated in Figure 4.

Clearly, each protein correlates to the length (number of amino acids) of protein. In general, a long protein would have a large value of f_i , which complicates the comparison between two heterogeneous proteins. Thus, we defined a new parameter, d_i , by normalizing f_i with the following equation:

¹Dipole Scale (Debye): —, Dipole < 1.0; +, 1.0 < Dipole < 2.0; ++, 2.0 < Dipole < 3.0; + + +, Dipole > 3.0; +′ +′ +′, Dipole > 3.0 with opposite orientation.

²Volume Scale (\AA^3): —, Volume < 50; +, Volume > 50.

³Cys is separated from class 3 because of its ability to form disulfide bonds.

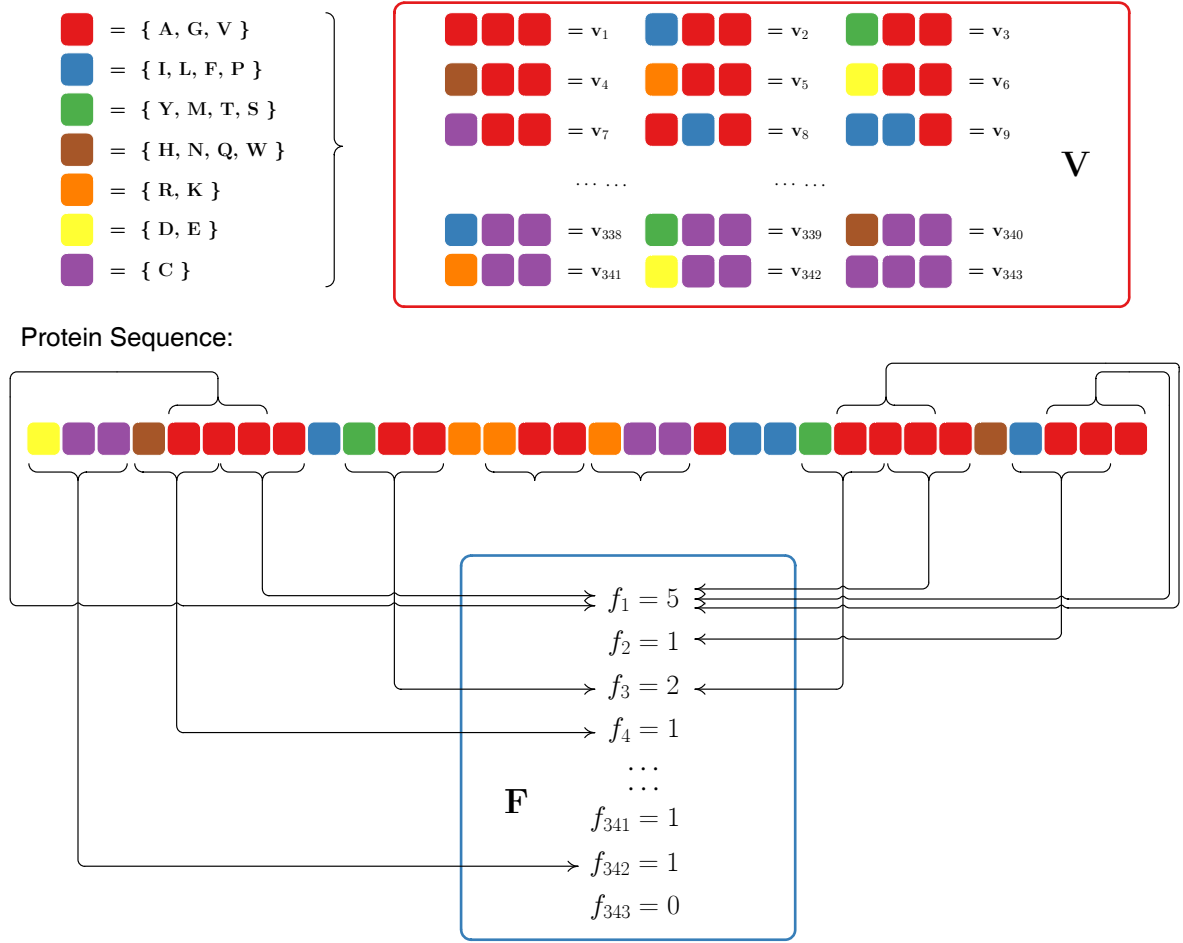

Figure 4: Schematic diagram for constructing the vector space (\mathbf{V}, \mathbf{F}) of protein sequence. \mathbf{V} is the vector space of the sequence features; each feature (v_i) represents a triad composed of three consecutive amino acids; \mathbf{F} is the frequency vector corresponding to \mathbf{V} , and the value of the i -th dimension of $\mathbf{F}(f_i)$ is the frequency that v_i triad appeared in the protein sequence.

$$d_i = \frac{f_i - \min\{f_1, f_2, \dots, f_{343}\}}{\max\{f_1, f_2, \dots, f_{343}\}}$$

The numerical value of d_i of each protein ranges from 0 to 1, which thereby enables the comparison between proteins. Accordingly, we obtain another vector space (designated **D**) consisting of d_i to represent protein.

To compute conjoint triads of protein sequences, we could simply use:

```
> ctriad = extractCTriad(x)
> head(ctriad, n = 65L)
```

```

by which we only outputted the first 65 of total 343 dimension to save space.

3.7. Quasi-sequence-order Descriptors

The quasi-sequence-order descriptors are proposed by [Chou \(2000\)](#). They are derived from the distance matrix between the 20 amino acids.

Sequence-order-coupling Number

The d -th rank sequence-order-coupling number is defined as:

$$\tau_d = \sum_{i=1}^{N-d} (d_{i,i+d})^2 \quad d = 1, 2, \dots, \text{maxlag}$$

where $d_{i,i+d}$ is the distance between the two amino acids at position i and $i + d$.

Note: maxlag is the maximum lag and the length of the protein must be not less than maxlag.

The function `extractSOCN(x)` is used for computing the sequence-order-coupling numbers:

```
> extractSOCN(x)
```

```
Schneider.lag1  Schneider.lag2  Schneider.lag3  Schneider.lag4  Schneider.lag5
      204.2036      199.8708      206.8102      197.4828      193.3366

6382281.0000	6276521.0000	6537634.0000	6442991.0000	6350157.0000

Users could also specify the maximum lag value with the `nlag` argument.

Note: In addition to Schneider-Wrede physicochemical distance matrix ([Schneider and Wrede 1994](#)) used by Kuo-Chen Chou, another chemical distance matrix by [Grantham \(1974\)](#) is also used here. So the descriptors dimension will be `nlag * 2`. The quasi-sequence-order descriptors described next also utilized the two matrices.

Quasi-sequence-order Descriptors

For each amino acid type, a quasi-sequence-order descriptor can be defined as:

$$X_r = \frac{f_r}{\sum_{r=1}^{20} f_r + w \sum_{d=1}^{\text{maxlag}} \tau_d} \quad r = 1, 2, \dots, 20$$

where f_r is the normalized occurrence for amino acid type i and w is a weighting factor ($w = 0.1$). These are the first 20 quasi-sequence-order descriptors. The other 30 quasi-sequence-order are defined as:

$$X_d = \frac{w\tau_{d-20}}{\sum_{r=1}^{20} f_r + w \sum_{d=1}^{\text{maxlag}} \tau_d} \quad d = 21, 22, \dots, 20 + \text{maxlag}$$

An minimal example for `extractQSO()` could be:

```
> extractQSO(x)
```

Figure 5: A schematic drawing to show (a) the 1st-rank, (b) the 2nd-rank, and (c) the 3rd-rank sequence-order-coupling mode along a protein sequence. (a) Reflects the coupling mode between all the most contiguous residues, (b) that between all the 2nd most contiguous residues, and (c) that between all the 3rd most contiguous residues. This figure is from [Chou \(2000\)](#).

where users could also specify the maximum lag with argument `nlag` and the weighting factor with argument `w`.

3.8. Pseudo-Amino Acid Composition (PAAC)

This groups of descriptors are proposed in [Chou \(2001\)](#). PAAC descriptors are also called the *type 1 pseudo-amino acid composition*. Let $H_1^o(i)$, $H_2^o(i)$, $M^o(i)$ ($i = 1, 2, 3, \dots, 20$) be the original hydrophobicity values, the original hydrophilicity values and the original side chain masses of the 20 natural amino acids, respectively. They are converted to following qualities by a standard conversion:

$$H_1(i) = \frac{H_1^o(i) - \frac{1}{20} \sum_{i=1}^{20} H_1^o(i)}{\sqrt{\frac{\sum_{i=1}^{20} [H_1^o(i) - \frac{1}{20} \sum_{i=1}^{20} H_1^o(i)]^2}{20}}}$$

$H_2^o(i)$ and $M^o(i)$ are normalized as $H_2(i)$ and $M(i)$ in the same way.

Then, a correlation function could be defines as

$$\Theta(R_i, R_j) = \frac{1}{3} \left\{ [H_1(R_i) - H_1(R_j)]^2 + [H_2(R_i) - H_2(R_j)]^2 + [M(R_i) - M(R_j)]^2 \right\}$$

This correlation function is actually an averaged value for the three amino acid properties: hydrophobicity value, hydrophilicity value and side chain mass. Therefore we can extend this definition of correlation function for one amino acid property or for a set of n amino acid properties.

For one amino acid property, the correlation can be defined as:

$$\Theta(R_i, R_j) = [H_1(R_i) - H_1(R_j)]^2$$

where $H(R_i)$ is the amino acid property of amino acid R_i after standardization.

Figure 6: A schematic drawing to show (a) the first-tier, (b) the second-tier, and (c) the third-tier sequence order correlation mode along a protein sequence. Panel (a) reflects the correlation mode between all the most contiguous residues, panel (b) that between all the second-most contiguous residues, and panel (c) that between all the third-most contiguous residues. This figure is from [Chou \(2001\)](#).

For a set of n amino acid properties, it can be defined as: where $H_k(R_i)$ is the k -th property in the amino acid property set for amino acid R_i .

$$\Theta(R_i, R_j) = \frac{1}{n} \sum_{k=1}^n [H_k(R_i) - H_k(R_j)]^2$$

where $H_k(R_i)$ is the k -th property in the amino acid property set for amino acid R_i .

A set of descriptors called sequence order-correlated factors are defined as:

$$\begin{aligned} \theta_1 &= \frac{1}{N-1} \sum_{i=1}^{N-1} \Theta(R_i, R_{i+1}) \\ \theta_2 &= \frac{1}{N-2} \sum_{i=1}^{N-2} \Theta(R_i, R_{i+2}) \\ \theta_3 &= \frac{1}{N-3} \sum_{i=1}^{N-3} \Theta(R_i, R_{i+3}) \\ &\dots \\ \theta_\lambda &= \frac{1}{N-\lambda} \sum_{i=1}^{N-\lambda} \Theta(R_i, R_{i+\lambda}) \end{aligned}$$

λ ($\lambda < L$) is a parameter to be chosen. Let f_i be the normalized occurrence frequency of the

20 amino acids in the protein sequence, a set of $20 + \lambda$ descriptors called the pseudo-amino acid composition for a protein sequence can be defines as:

$$X_c = \frac{f_c}{\sum_{r=1}^{20} f_r + w \sum_{j=1}^{\lambda} \theta_j} \quad (1 < c < 20)$$

$$X_c = \frac{w\theta_{c-20}}{\sum_{r=1}^{20} f_r + w \sum_{j=1}^{\lambda} \theta_j} \quad (21 < c < 20 + \lambda)$$

where w is the weighting factor for the sequence-order effect and is set as $w = 0.05$ in **protr** as suggested by Kuo-Chen Chou.

With `extractPAAC()`, we could compute the PAAC descriptors:

```
> extractPAAC(x)
```

The `extractPAAC()` function also provides the `props` and `customprops` arguments, which is similar to the functions for Moreau-Broto/Moran/Geary autocorrelation descriptors. For minor differences, see `?extracPAAC`. Users could specify the lambda parameter and the weighting factor with arguments `lambda` and `w`.

Note: In the work of Kuo-Chen Chou, the definition for “normalized occurrence frequency” was not given. In this work, we define it as the occurrence frequency of amino acid in the sequence normalized to 100% and hence our calculated values are not the same as values by them.

3.9. Amphiphilic Pseudo-Amino Acid Composition (APAAC)

Amphiphilic Pseudo-Amino Acid Composition (APAAC) was proposed in Chou (2001). APAAC is also recognized as the *type 2 pseudo-amino acid composition*. The definitions of these qualities are similar to the PAAC descriptors. From $H_1(i)$ and $H_2(j)$ defined before, the hydrophobicity and hydrophilicity correlation functions are defined respectively as:

$$\begin{aligned} H_{i,j}^1 &= H_1(i)H_1(j) \\ H_{i,j}^2 &= H_2(i)H_2(j) \end{aligned}$$

From these qualities, sequence order factors can be defines as:

$$\begin{aligned} \tau_1 &= \frac{1}{N-1} \sum_{i=1}^{N-1} H_{i,i+1}^1 \\ \tau_2 &= \frac{1}{N-1} \sum_{i=1}^{N-1} H_{i,i+1}^2 \\ \tau_3 &= \frac{1}{N-2} \sum_{i=1}^{N-2} H_{i,i+2}^1 \\ \tau_4 &= \frac{1}{N-2} \sum_{i=1}^{N-2} H_{i,i+2}^2 \\ &\dots \\ \tau_{2\lambda-1} &= \frac{1}{N-\lambda} \sum_{i=1}^{N-\lambda} H_{i,i+\lambda}^1 \\ \tau_{2\lambda} &= \frac{1}{N-\lambda} \sum_{i=1}^{N-\lambda} H_{i,i+\lambda}^2 \end{aligned}$$

Then a set of descriptors called *Amphiphilic Pseudo-Amino Acid Composition* (APAAC) are defined as:

$$P_c = \frac{f_c}{\sum_{r=1}^{20} f_r + w \sum_{j=1}^{2\lambda} \tau_j} \quad (1 < c < 20)$$

$$P_c = \frac{w\tau_u}{\sum_{r=1}^{20} f_r + w \sum_{j=1}^{2\lambda} \tau_j} \quad (21 < u < 20 + 2\lambda)$$

where w is the weighting factor and is taken as $w = 0.5$ in **protr** as in the work of Chou KC. A minimal example for **extractAPAAC()** is:

```
> extractAPAAC(x)
```

This function has the same arguments as `extractPAAC()`.

3.10. Profile-based Descriptors

The profile-based descriptors for protein sequences are available in the **protr** package. The feature vectors of profile-based methods were based on the PSSM by running PSI-BLAST, and often show good performance. See [Ye *et al.* \(2011\)](#) and [Rangwala and Karypis \(2005\)](#) for details. The functions `extractPSSM()`, `extractPSSMAcc()` and `extractPSSMFeature()` are used to generate these descriptors. Users need to install the NCBI-BLAST+ software package first to make the functions fully functional.

4. Descriptors for Proteochemometric Modeling

Proteochemometric (PCM) modeling utilizes statistical modeling techniques to model ligand-target interaction space. The below descriptors implemented in **protr** are extensively used in Proteochemometric modeling.

- Scales-based descriptors derived by Principal Components Analysis
 - Scales-based descriptors derived by Amino Acid Properties from AAindex (Protein Fingerprint)
 - Scales-based descriptors derived by 20+ classes of 2D and 3D molecular descriptors (Topological, WHIM, VHSE, etc.)
- Scales-based descriptors derived by Factor Analysis
- Scales-based descriptors derived by Multidimensional Scaling
- BLOSUM and PAM matrix-derived descriptors

Note that each of the scales-based descriptor functions are freely to combine with the more than 20 classes of 2D and 3D molecular descriptors to construct highly customized scales-based descriptors. Of course, these functions are designed to be flexible enough that users could provide totally self-defined property matrices to construct scales-based descriptors.

For example, to compute the “topological scales” derived by PCA (using the first 5 principal components), one could use `extractDescScales()`:

```
> x = readFASTA(system.file('protseq/P00750.fasta', package = 'protr'))[[1]]
> descscscales = extractDescScales(x, propmat = 'AATopo',
+                                index = c(37:41, 43:47),
+                                pc = 5, lag = 7, silent = FALSE)
```

Summary of the first 5 principal components:

	PC1	PC2	PC3	PC4	PC5
Standard deviation	2.581537	1.754133	0.4621854	0.1918666	0.08972087
Proportion of Variance	0.666430	0.307700	0.0213600	0.0036800	0.00080000
Cumulative Proportion	0.666430	0.974130	0.9954900	0.9991700	0.99998000

the argument `propmat` involves the **AATopo** dataset shipped with **protr** package, and the argument `index` selects the 37 to 41 and the 43 to 47 columns (molecular descriptors) in the **AATopo** dataset to use, the parameter `lag` was set for the Auto Cross Covariance (ACC) for generating scales-based descriptors of the same length. At last, we printed the summary of the first 5 principal components (standard deviation, proportion of variance, cumulative proportion of variance).

The result is a length 175 named vector, which is consistent with the descriptors before:

```
> length(descscales)
```

```
[1] 175
```

```
> head(descscales, 15)
```

```

      scl1.lag1      scl2.lag1      scl3.lag1      scl4.lag1      scl5.lag1
-2.645644e-01 -1.717847e-02  1.975438e-02 -7.930659e-05 -3.710597e-05
      scl1.lag2      scl2.lag2      scl3.lag2      scl4.lag2      scl5.lag2
 3.548612e-01  1.343712e-01  5.699395e-03 -5.489472e-04 -6.364577e-05
      scl1.lag3      scl2.lag3      scl3.lag3      scl4.lag3      scl5.lag3
 2.011431e-02 -9.211136e-02 -1.461755e-03  6.747801e-04  2.386782e-04
```

For another example, to compute the descriptors derived by BLOSUM62 matrix and use the first 5 scales, one could use:

```
> x = readFASTA(system.file('protseq/P00750.fasta', package = 'protr'))[[1]]
> blosum = extractBLOSUM(x, submat = 'AABLOSUM62',
+                          k = 5, lag = 7, scale = TRUE, silent = FALSE)
```

Relative importance of all the possible 20 scales:

```

[1] 1.204960e+01 7.982007e+00 6.254364e+00 4.533706e+00 4.326286e+00
[6] 3.850579e+00 3.752197e+00 3.538207e+00 3.139155e+00 2.546405e+00
[11] 2.373286e+00 1.666259e+00 1.553126e+00 1.263685e+00 1.024699e+00
[16] 9.630187e-01 9.225759e-01 7.221636e-01 1.020085e-01 5.868878e-16
```

The result is a length 175 named vector:

```
> length(blosum)
```

```
[1] 175
```

```
> head(blosum, 15)
```

scl1.lag1	scl2.lag1	scl3.lag1	scl4.lag1	scl5.lag1

-0.0014919096	0.0032873726	0.0011734162	-0.0021758536	-0.0018127568
scl1.lag3	scl2.lag3	scl3.lag3	scl4.lag3	scl5.lag3
-0.0029413528	0.0001494193	0.0003298806	-0.0017877430	-0.0051044133

Dealing with gaps. In proteochemometrics, (sequence alignment) gaps can be very useful, since a gap in a certain position contains information. The **protr** package has built-in support for such gaps. We deal with the gaps by using a dummy descriptor to code for the 21st type of amino acid. The function `extractScalesGap()` and `extractProtFPGap()` could be used to deal with such gaps. See `?extractScalesGap` and `?extractProtFPGap` for details.

5. Similarity Calculation by Sequence Alignment

Similarity computation derived by local or global protein sequence alignment between a list of protein sequences is great need in the protein related research and applications. However, this sort of pairwise similarity computation often computationally intensive, especially when there exists many protein sequences. Luckily, this process is also highly parallelizable, the **protr** package integrates the function of parallelized similarity computation derived by local or global protein sequence alignment between a list of protein sequences.

The function `twoSeqSim()` calculates the alignment result between two protein sequences, and the function `parSeqSim()` calculates the pairwise similarity calculation with a list of protein sequences in parallel:

```
> s1 = readFASTA(system.file('protseq/P00750.fasta', package = 'protr'))[[1]]
> s2 = readFASTA(system.file('protseq/P08218.fasta', package = 'protr'))[[1]]
> s3 = readFASTA(system.file('protseq/P10323.fasta', package = 'protr'))[[1]]
> s4 = readFASTA(system.file('protseq/P20160.fasta', package = 'protr'))[[1]]
> s5 = readFASTA(system.file('protseq/Q9NZP8.fasta', package = 'protr'))[[1]]
> plist = list(s1, s2, s3, s4, s5)
> psimmat = parSeqSim(plist, cores = 4, type = 'local', submat = 'BLOSUM62')
> print(psimmat)
```

	[,1]	[,2]	[,3]	[,4]	[,5]
[1,]	1.00000000	0.11825938	0.10236985	0.04921696	0.03943488
[2,]	0.11825938	1.00000000	0.18858241	0.12124217	0.06391103
[3,]	0.10236985	0.18858241	1.00000000	0.05819984	0.06175942
[4,]	0.04921696	0.12124217	0.05819984	1.00000000	0.05714638
[5,]	0.03943488	0.06391103	0.06175942	0.05714638	1.00000000

It should be noted that for a small number of proteins, calculating their pairwise similarity scores derived by sequence alignment in parallel may not significantly reduce the overall computation time, since each of the task only requires a relatively small time to finish, thus,

computational overheads may exist and affect the performance. In testing, we used about 1,000 protein sequences on 64 CPU cores, and observed significant performance improvement comparing to the sequential computation.

Users should install the packages **foreach** and **doParallel** before using `parSeqSim()`, according to their operation system. The **protr** package will automatically decide which backend to use.

6. Similarity Calculation by GO Semantic Similarity Measures

The **protr** package also integrates the function of similarity score computation derived by Gene Ontology (GO) semantic similarity measures between a list of GO terms / Entrez Gene IDs.

The function `twoGOSim()` calculates the similarity derived by GO-terms semantic similarity measures between two GO terms / Entrez Gene IDs, and the function `parGOSim()` calculates the pairwise similarity with a list of GO terms / Entrez Gene IDs:

```
# by GO Terms
> go1 = c('GO:0005215', 'GO:0005488', 'GO:0005515',
+         'GO:0005625', 'GO:0005802', 'GO:0005905') # AP4B1
> go2 = c('GO:0005515', 'GO:0005634', 'GO:0005681',
+         'GO:0008380', 'GO:0031202') # BCAS2
> go3 = c('GO:0003735', 'GO:0005622', 'GO:0005840',
+         'GO:0006412') # PDE4DIP
> glist = list(go1, go2, go3)
> gsimmat1 = parGOSim(glist, type = 'go', ont = 'CC')
> print(gsimmat1)

      [,1] [,2] [,3]
[1,] 1.000 0.077 0.055
[2,] 0.077 1.000 0.220
[3,] 0.055 0.220 1.000

# by Entrez gene id
> genelist = list(c('150', '151', '152', '1814', '1815', '1816'))
> gsimmat2 = parGOSim(genelist, type = 'gene')
> print(gsimmat2)

1816 0.160 0.274 0.198 0.411 0.481 0.819
```

7. ProtrWeb

The web service built on **protr**, namely **ProtrWeb**, is located at:

<http://protr.org>

ProtrWeb (Figure 8) does not require any knowledge of programming for the users, it is a user-friendly and one-click-to-go online platform for computing the protein descriptors presented in the **protr** package.

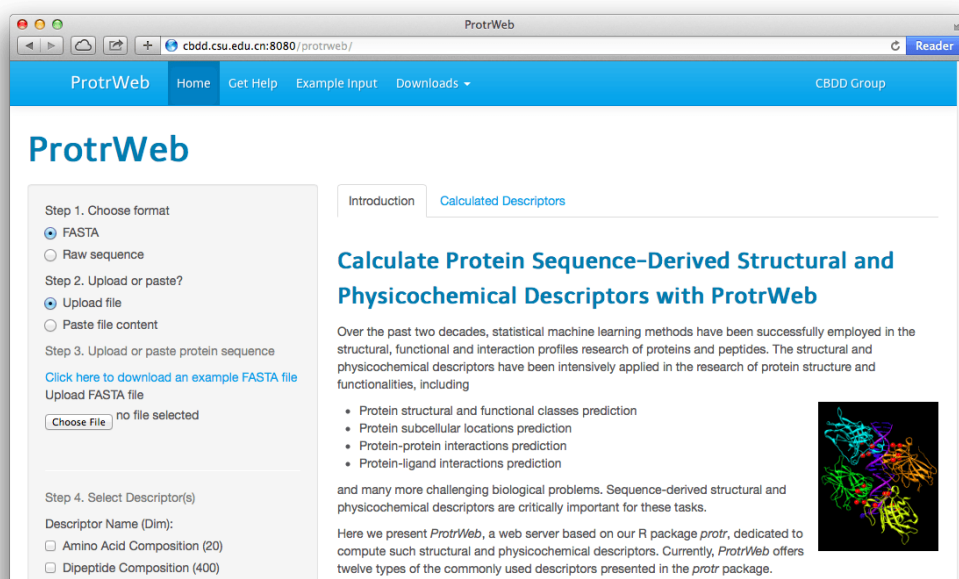

Figure 8: A screenshot of the web server **ProtrWeb**

A step-by-step instruction on how to use **ProtrWeb** could be found at:

<http://protr.org/intro.html>

8. Miscellaneous Tools

In this section, we will briefly introduce some useful tools provided by the **protr** package.

8.1. Retrieve Protein Sequences from UniProt

This function `getUniProt()` gets protein sequences from uniprot.org by protein ID(s). The input `ID` is a character vector specifying the protein ID(s). The returned sequences are stored in a list:

```
> ids = c('P00750', 'P00751', 'P00752')
> prots = getUniProt(ids)
> print(prots)
```

```

8.2. Read FASTA Format files

The `readFASTA()` function provides a convenient way to read protein sequences stored in FASTA format files. See `?readFASTA` for details. The returned sequences are stored in a named list, whose components are named with the protein sequences' names.

8.3. Read PDB Format files

The Protein Data Bank (pdb) file format is a textual file format describing the three dimensional structures of protein. The `readPDB()` function provides the function to read protein sequences stored in PDB format files. See `?readPDB` for details.

8.4. Sanity Check of the Amino Acid Types

The `protcheck()` function checks if the protein sequence's amino acid types are in the 20 default types, which returns a `TRUE` if all the amino acids in the sequence belongs to the 20 default types:

```
> x = readFASTA(system.file('protseq/P00750.fasta', package = 'protr'))[[1]]
```

```
> # A real sequence
> protcheck(x)

[1] TRUE

> # An artificial sequence
> protcheck(paste(x, 'Z', sep = ''))

[1] FALSE
```

8.5. Protein Sequence Partition

The `protseg()` function partitions the protein sequences to create sliding windows. This is usually required when creating feature vectors for machine learning tasks. Users could specify a sequence `x`, and a character `aa`, one of the 20 amino acid types, and a positive integer `k`, which controls the window size (half of the window).

This function returns a named list, each component contains one of the segmentations (a character string), names of the list components are the positions of the specified amino acid in the sequence. See the example below:

```
> protseg(x, aa = 'M', k = 5)

$`48`
[1] "DEKTQMIYQQH"

$`242`
[1] "LPWNSMILIGK"

$`490`
[1] "TVTDNMLCAGD"

$`525`

```

8.6. Auto Cross Covariance (ACC) Computation

Auto Cross Covariance (ACC) is extensively used in the scales-based descriptors computation, this approach calculates the auto covariance and auto cross covariance for generating scale-based descriptors of the same length. Users could write their own scales-based descriptor functions with the help of `acc()` function in the **protr** package.

8.7. Pre-computed 2D and 3D Descriptor Sets for the 20 Amino Acids

The **protr** package ships with more than 20 pre-computed 2D and 3D descriptor sets for the 20 amino acids to use with the scales-based descriptors, see `data(package = 'protr')` for all the datasets included in the **protr** package.

8.8. BLOSUM and PAM Matrices for the 20 Amino Acids

The BLOSUM and PAM matrices for the 20 amino acids could be used to calculate BLOSUM and PAM matrix-derived descriptors with function `extractBLOSUM()`, the datasets are named in `AABLOSUM45`, `AABLOSUM50`, `AABLOSUM62`, `AABLOSUM80`, `AABLOSUM100`, `AAPAM30`, `AAPAM40`, `AAPAM70`, `AAPAM120`, and `AAPAM250`.

8.9. Meta Information of the 20 Amino Acids

As the reference, the `AAMetaInfo` dataset includes the meta information of the 20 amino acids used for the 2D and 3D descriptor calculation in the **protr** package. This dataset include each amino acid's name, one-letter representation, three-letter representation, SMILE representation, PubChem CID and PubChem link. See `data(AAMetaInfo)` for details.

9. Summary

The summary of the descriptors in the **protr** package is listed in table 3.

Table 3: List of commonly used descriptors in **protr**

Descriptor Group	Descriptor Name	Descriptor Dimension	Function Name
Amino Acid Composition	Amino Acid Composition	20	<code>extractAAC()</code>
	Dipeptide Composition	400	<code>extractDC()</code>
	Tripeptide Composition	8000	<code>extractTC()</code>
Autocorrelation	Normalized Moreau-Broto Auto-correlation	240 ¹	<code>extractMoreauBroto()</code>
	Moran Autocorrelation	240 ¹	<code>extractMoran()</code>
	Geary Autocorrelation	240 ¹	<code>extractGeary()</code>
CTD	Composition	21	<code>extractCTDC()</code> , <code>extractCTDCClass()</code>
	Transition	21	<code>extractCTDT()</code> , <code>extractCTDTCClass()</code>
	Distribution	105	<code>extractCTDD()</code> , <code>extractCTDDClass()</code>
Conjoint Triad	Conjoint Triad	343	<code>extractCTriad()</code> , <code>extractCTriadClass()</code>
Quasi-Sequence-Order	Sequence-Order-Coupling Number	60 ²	<code>extractSOCN()</code>
	Quasi-Sequence-Order Descriptors	100 ²	<code>extractQS0()</code>
Pseudo-Amino Acid Composition	Pseudo-Amino Acid Composition	50 ³	<code>extractPAAC()</code>
	Amphiphilic Pseudo-Amino Acid Composition	80 ⁴	<code>extractAPAAC()</code>

The summary of the scales-based PCM descriptors in the **protr** package is listed in table 4.

The summary of the amino acid descriptor sets used by scales-based descriptors provided in the **protr** package is listed in table 5. Note that the non-informative descriptors (like the descriptors have only one value across all the 20 amino acids) in these datasets have already

¹The number depends on the choice of the number of properties of amino acids and the choice of the maximum values of the `lag`. The default is use 8 types of properties and `lag = 30`.

²The number depends on the maximum value of `lag`. By default `lag = 30`. And two distance matrices were used, so the descriptor dimension is $30 \times 2 = 60$ and $(20 + 30) \times 2 = 100$.

³The number depends on the choice of the number of the set of amino acid properties and the choice of the λ value. The default is use 3 types of properties proposed by Kuo-Chen Chou and $\lambda = 30$.

⁴The number depends on the choice of the λ vlaue. The default is that $\lambda = 30$.

Table 4: List of PCM descriptors in **protr**

Derived by	Descriptor Class	Function Name
Principal Components Analysis	Scales-based descriptors derived by Principal Components Analysis	<code>extractScales()</code> , <code>extractScalesGap()</code>
	Scales-based descriptors derived by amino acid properties from AAindex (a.k.a. Protein Fingerprint)	<code>extractProtFP()</code> , <code>extractProtFPGap()</code>
	Scales-based descriptors derived by 2D and 3D molecular descriptors (Topological, WHIM, VHSE, etc.)	<code>extractDescScales()</code>
Factor Analysis	Scales-based descriptors derived by Factor Analysis	<code>extractFAScales()</code>
Multidimensional Scaling	Scales-based descriptors derived by Multidimensional Scaling	<code>extractMDSScales()</code>
Substitution Matrix	BLOSUM and PAM matrix-derived descriptors	<code>extractBLOSUM()</code>

been filtered out.

In this manual, we discussed the functions of the **protr** package, which is trying to offer a comprehensive and unique toolkit for protein sequence descriptor calculation and similarity computation.

Acknowledgments

This work is financially supported by the National Natural Science Foundation of China (Grant No. 11271374) and the Postdoctoral Science Foundation of Central South University. The studies meet with the approval of the university's review board.

Table 5: List of the pre-calculated descriptor sets of the 20 amino acids in **protr**

Dataset Name	Descriptor Set Name	Dimensionality	Calculated by
AA2DACOR	2D Autocorrelations Descriptors	92	Dragon
AA3DMoRSE	3D-MoRSE Descriptors	160	Dragon
AAACF	Atom-Centred Fragments Descriptors	6	Dragon
